

3.2.5 Summary and Generalization

For all three cases of polarization mechanisms, we had a **linear** relationship between the electrical field and the dipole moment (for fields that are not excessively large):

Electronic polarization

$$\mu_{EP} = 4\pi \cdot \epsilon_0 \cdot R^3 \cdot E$$

Ionic polarization

$$\mu_{IP} = \frac{q^2}{k_{IP}} \cdot E$$

Orientation polarization

$$\mu_{OP} = \frac{\mu^2}{3kT} \cdot E$$

It seems on a first glance that we have justified the "law" $P = \chi \cdot E$.

- However, that is not quite true at this point. In the "law" given by equation above, E refers to the **external** field, i.e. to the field that would be present in our capacitor **without** a material inside.
- We have $E_{ex} = U/d$ for our plate capacitor held at a voltage U and a spacing between the plates of d .
- On the other hand, the induced dipole moment that we calculated, always referred to the **field at the place of the dipole**, i.e. the **local** field E_{loc} . And if you think about it, you should at least feel a bit uneasy in assuming that the two fields are identical. We will see about this in the next paragraph.

Here we can only define a factor that relates μ and E_{loc} ; it is called the **polarizability** α . It is rarely used with a number attached, but if you run across it, be careful if ϵ_0 is included or not; in other words what kind of **unit system** is used.

- We now can reformulate the three equations on top of this paragraph into one equation

$$\underline{\mu} = \alpha \cdot E_{loc}$$

- The **polarizability** α is a material parameter which depends on the polarization mechanism: For our three paradigmatic cases they are given by

$$\alpha_{EP} = 4\pi \cdot \epsilon_0 \cdot R^3$$

$$\alpha_{IP} = \frac{q^2}{k_{IP}}$$

$$\alpha_{OP} = \frac{\mu^2}{3kT}$$

- This does not add anything new but emphasizes the proportionality to E .

So we **almost** answered our **first basic question** about dielectrics - but for a full answer we need a relation between the **local** field and the **external** field. This, unfortunately, is **not a particularly easy problem**

- One reason for this is: Whenever we talk about electrical fields, we always have a certain scale in mind - without necessarily being aware of this. Consider: In a metal, as we learn from electrostatics, there is **no field at all**, but that is **only true** if we do not look too closely. If we look on an **atomic scale**, there are tremendous fields between the nucleus and the electrons. At a somewhat larger scale, however, they disappear or perfectly balance each other (e.g. in ionic crystals) to give no field on somewhat larger dimensions.
- The scale we need here, however, is the **atomic scale**. In the electronic polarization mechanism, we actually "looked" **inside** the atom - so we shouldn't just stay on a "rough" scale and neglect the fine details.

Nevertheless, that is what we are going to do in the next paragraph: **Neglect the details**. The approach may not be beyond reproach, but it works and gives simple relations.
